#### 1. Interpreters and Language Semantics (18 points)

Appendix A contains the complete code for a variant of one of the SIMPLE imperative language interpreters we explored in class. This version includes a new "for-loop" construct. The new abstract syntax (on line 15) is For(x, e, c), which is intended to have a semantics like the following c program:

```
for(x=0; x != e; x=x+1) {
   c;
}
```

Here, x is a variable, e is an expression, and c is the body of the loop. (Unlike more fully-featured forloops, this version only allows for x to be incremented by 1 and requires the loop guard to test inequality with respect to the expression e.)

(a) (4 points) The OCaml definition factorial\_for gives the abstract syntax tree for a SIMPLE program that uses a for loop. Translate it into c (-like) concrete syntax. (Since all of the types are integers, there is no need to mention type information.)

(b) (4 points) Consider the program For ("x", Imm 5, c). Does the semantics of For loops given by interp\_cmd ensure that the command c will be executed exactly 5 times? Why or why not?

(c) (6 points) The interp\_cmd function in Appendix A uses OCaml meta-level constructs to implement the loop semantics (see lines 49–59). An alternative is to "desugar" the For abstract syntax node into an equivalent command that does not mention For and then interpret that (as is done to handle WhileNZ on line 47). What code would replace lines 50–59 to desugar For(x, e, c)?

49 | For(x, e, c) ->

(d) (4 points) Suppose that instead of *interpreting* this language, we were *compiling* it to LLVM IR. The parser could desugar For immediately, so that we do not even need to include it as part of the abstract syntax. Describe one reason why the compiler might *not* want to do that.

## 2. X86 and Calling Conventions (16 points)

The following code computes the trace (i.e., the sum of the diagonal entries) of a square matrix, in C (left), and X86 assembly (right). (Recall that the c type long is a 64-bit integer value.)

		trace:				
			movq movq movq	\$0, \$0, %rsi,	%rax %rdx %rcx	
	<pre>long trace(unsigned long n,</pre>		movq	%rdi,	%r10	
	long m[n][n]) {		imulq	-	%r10	
	long i;		addq	\$8,	%r10	
	<pre>long i, long result = 0;</pre>	loop:	aaaq	ΨΟ,	701 10	
	for (i = 0; i < n; i++) {	1006.	cmpq	%rdi,	%rdx	
	result += m[i][i];		jl	body	70. GX	
	}		retq	~ ~ ~ ,		
	return result;					
	}	body:				
	,	,	addq	(%rcx)	, %rax	
			addq	\$1,	%rdx	
			addq	%r10,	%rcx	
			jmp	loop		
(a)	The parameter n is passed to trace in the following location $\Box$ -16(%rbp) $\Box$ %rdi $\Box$ %rsi	(choose or		%rax		
(b)	$\Box$ True or $\Box$ False: The contents of the matrix m are laid of	out contigu	ously in	n memor	y	
(c)	The value of i is stored in the following location (choose one	)				
	□ -16(%rbp) □ %rax □ %rdx		□ %	%r10		
	, ,,					
(d)	Suppose that we call trace with n=3. When trace exits, the c-language expression? (choose one)	e value sto	red in r	cx is equ	al to which	ch
	$\square$ 2 $\square$ ((long*)m + 12) $\square$ m[2][2] $\square$	((long*	)m + 9	6)		
(e)	☐ True or ☐ False: According to the cdecl standard, %rbp	is a calle	e-save re	egister.		
(f)	$\ \square$ True or $\ \square$ False: X86 code is structured as <i>basic blocks</i> , code, and terminator instructions.	with label	ed entry	points,	straight-lii	ne
(g)	(4 points) Write a sequence of X86lite instructions that has thusing pushq:	he same ef	fect as	pushq %	rcx witho	ut

#### 3. LLVM IR (20 points)

Consider the following C code (left), and corresponding LLVMlite (right):

- (a) (2 points) How many bytes does an LLVM value of type [5 x %C\*] occupy?
- (b) (2 points) How many bytes does an LLVM value of type [5 x %A] occupy?
- (c) (10 points) Consider the following c statement (where a is of type A\*):

```
int64_t x = (*a).foot[3] + (*a).c.y;
```

Suppose that %a is the LLVM uid of type %A\* corresponding to the value stored in a. Fill in the blanks of the following LLVM IR snippet so that it corresponds to the c statement above. (The comments indicate the what sort of missing information should be filled in.)

```
%x = alloca ______ ; LLVM type
%tmp1 = getelementptr %A* %a, ______ ; GEP path
%val1 = load i64, ______ ; LLVM type and uid
%tmp2 = getelementptr %A* %a, ______ ; GEP path
%val2 = load i64, ______ ; LLVM type and uid
%val3 = _____ i64 %val1, %val2 ; LLVM binop instruction
store i64 %val3, _____ %x ; LLVM type
```

(d) (4 points) In your LLVMlite-to-x86lite code generator, the stack layout assigns each uid a stack slot that is referenced by a constant (negative) offset from rbp. Could you instead reference stack slots by a constant (positive) offset from rsp? Why or why not?

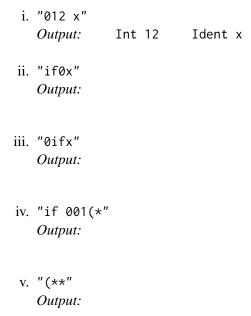

(e) (2 points) In a LLVM control flow graph with N vertices, what is the maximum number of edges?

-

4.	Lexing	(16)	points)

Appendix B has the ocamllex code for a simple lexer program based on the ones we have seen in class.

(a) (2 points each) For each of the following input strings provided on stdin, what output sequence would be printed by the lexer? If the lexer generates an error anywhere during its operation, write "Char X is unexpected." where X is the illegal character. (Unlike the real program, which prints one token per line, you can put the output on one line.) We have done the first one for you.

(b) (4 points) Suppose that you wanted to modify the lexer so that identifiers can (but do not have to) start with an underscore. Which line (or lines) of the lexer code would you modify and what change would you make?

(c) (4 points) Is it possible for the DFA corresponding to an NFA to have *fewer* states? If so, give an example. If not, briefly explain why.

### 5. Parsing (20 points)

(a) (3 points) Is it possible to construct a context free grammar that accepts exactly the set of well-formed LLVM IR programs? Why or why not?

Consider the following context free grammar with terminals  $\{x, y, z, \$\}$  and non-terminals S', S and T. S is the starting nonterminal and \$ is the end-of-input marker.

$$\begin{array}{ccc} S' & \longrightarrow & S\$ \\ S & \longrightarrow & xST \\ S & \longrightarrow & \epsilon \\ T & \longrightarrow & yT \end{array}$$

- (b) (3 points) Which of the following strings are accepted by this grammar? (Mark all such strings)
  - $\Box \ \epsilon \qquad \Box \ xyz \qquad \Box \ xzy \qquad \Box \ xyzyz \qquad \Box \ xxyzyz$
- (c) (3 points) Is this grammar LL(1)? Why or why not?

(d) (2 points) What is Follow(S), the follow set of nonterminal S, for this grammar?

Follow(S) =

For your reference, here is the same grammar again:  $\begin{array}{ccc} S & \longrightarrow & xST \\ S & \longrightarrow & \epsilon \end{array}$ 

 $T \longrightarrow yT$   $T \longrightarrow yz$ 

(e) (6 points) Complete the DFA for the state space corresponding to the LR(0) parser for this grammar. Each state is numbered and consists of a set of LR(0) items. State (a) is the start state. You need to fill in the items for state (4) and the missing labels for the three edges originating at state (6). *Hint:* the items in state (4) do not indicate any reduce actions.

$$\begin{cases}
S' & \to & \cdot S\$ \\
S & \to & \cdot xST
\end{cases} \xrightarrow{S} \begin{cases}
S & \to & \cdot xST
\end{cases} \xrightarrow{S} \begin{cases}
